説明

Disclosed is a twisted-string based hair removing device, comprising: a pair of curved arms with pivoting sections pivotally coupled together by a pivot pin to allow free ends of the arms to selectively open and close. A pair of string guides is provided on adjacent tips of the free ends and each string guide forms a guide slot. The opposite ends, which form force-applying sections, comprises at least one fastening section and forms a pair of guide plates on their adjacent tips, each guide plate forming a guide slot. A spring has opposite ends coupled to opposing edges of the curved arms to provide potential energy for closing the free ends. A string has a central section received and retained in the guide slots of the guide plates formed on the free ends of the curved arm and is self-twisted by making a plurality of turns of twisting to form a twisted section. Opposite ends of the string are routed through the guide slots of the guide plates of the force-applying sections and are each secured to the fastening portion by a resilient element.
