説明

An emergency brake hazard warning flasher initiates the hazard warning lights as an emergency braking is applied. This device directly uses vehicle's battery as a power source. As an emergency brake or sudden deceleration occurs, this device will lock the battery's power by an inertia switch. Then generates pulse power in a short period. And lights up the hazard warning lights in pulse form. This device is installed inside the engine room. The generated pulse power is inputted to the front hazard warning lamps. The power of the rear hazard warning lamps is obtained from that of the front hazard warning lamps since both ends of the lamps have power lines linked together.
